Abstract

We study finite energy static solutions to a global symmetry breaking Goldstone model described by an isovector scalar field in $D + 1$ spacetime dimensions. Both topologically stable multisolitons with arbitrary winding numbers, and zero topological charge soliton–antisoliton solutions are constructed numerically in $D = 3, 4, 5$. We have explored the types of symmetries the systems should be subjected to, for there to exist multisoliton and soliton–antisoliton pairs in $D = 3, 4, 5, 6$. These findings are underpinned by constructing numerical solutions in the $D \leq 5$ examples. Subject to axial symmetry, only multisolitons of all topological charges exist in *even* D , and in *odd* D , only zero and unit topological charge solutions exist. Subjecting the system to weaker than axial symmetries, results in the existence of all the possibilities in all dimensions. Our findings apply also to finite ‘energy’ solutions to Yang–Mills and Yang–Mills–Higgs systems, and in principle also sigma models.

1 Introduction

Very early in the history of field theory solitons, interest in the existence of zero topological charge solutions arose. In the case of the Yang–Mills (YM) instantons [1] in $D = 4$ Euclidean space, which are selfdual, this raised the question of existence of non-selfdual [2, 3, 4] solutions, while even earlier this question was investigated [5] in the case of magnetic monopoles of the YM-Higgs (YMH) model in $D = 3$. More recently, concrete numerical constructions of monopole–antimonopole solutions [7, 8, 9] to the YMH model in $D = 3$, instanton–antiinstanton solutions [10] to the YM model in $D = 4$, as well as soliton–antisoliton solutions [11] to a Goldstone model in $D = 3$, were given.

The potential relevance of field theory soliton–antisolitons in higher dimensions rests in the fact that they describe on BPS field configurations that may be useful in the description of brane–antibrane configurations. Such solutions can be the zero topological charge counterparts of higher dimensional instantons [13] and of monopoles [14], or of the solitons of the symmetry breaking Goldstone type models [15] arising as the gauge decoupling limits of higher dimensional monopole models [14]. These Goldstone models have not found any physical applications to date, but as prototype systems modeling higher dimensional monopoles without the burden of gauge degrees of freedom, they can be useful for example in providing backgrounds on which Dirac equations [16] in all dimensions can be solved, or possibly also for gravitating monopoles. Here, they will prove very useful in studying zero topological charge solutions in higher dimensions.

Zero topological charge solutions to such a Goldstone model in $D = 3$ were recently given in [11]. The model in [11] is the gauge decoupling limit of the YMH model descending from the $p = 2$ member of the YM hierarchy introduced in [13] and is the simplest example. In the present paper we will extend this study to the Goldstone model descending from the $p = 3$ member of the YM hierarchy. In contrast to the $p = 2$ Goldstone model which supports finite energy solitons only in $D = 3$, the $p = 3$ Goldstone model enables us to study solutions in dimensions $D = 3, 4, 5$, allowed by the Derrick scaling rule. This is very important for our purposes here as will be explained below. As such, the $p = 3$ Goldstone model will serve as a vehicle for us to investigate zero topological solutions in the simplest possible technical setting.

The main objective of this work is to find out: subject to what symmetries and for what boundary conditions do such solutions exist? We have presented several numerically constructed solutions in dimensions $D \leq 5$, by way of underpinning our findings. While our symmetry considerations cover the dimensions $3 \leq D \leq 6$, the concrete numerical constructions are limited to $D = 3, 4, 5$ in the $p = 3$ Goldstone model, covering both even and odd dimensions, allowing us to make a classification of the said conditions. Our study addresses the question as to what are the requisite ingredients in the construction of zero topological charge solitons in higher dimensions, highlighting the distinction between even and odd dimensions in this respect. We find that such solutions can be accommodated by imposing the requisite boundary conditions for systems subject to the appropriate symmetry, in all dimensions. Stated most succinctly, subject to axial symmetry only multisolitons of arbitrary charges exist in even D , while in odd D zero and unit topological charge solutions can exist. By imposing less stringent symmetries than axial, all possible types of solutions can be constructed in any dimension.

The symmetries considered are at one extreme *axial*, namely spherical symmetry in a \mathbb{R}^{D-1} subspace of \mathbb{R}^D , and at the other *azimuthal*, namely rotational symmetry in a \mathbb{R}^2 subspace of \mathbb{R}^D . In between, we have explored the imposition of all *intermediate* cases, namely imposition of rotational symmetry in all the other subspaces \mathbb{R}^n of \mathbb{R}^D . In addition, we have considered imposition of multi-azimuthal symmetries on all \mathbb{R}^2 subspaces of \mathbb{R}^D .

Concerning the numerical constructions, our reason for limiting to the $p = 3$ Goldstone model, and to $D \leq 5$, is that otherwise it would be necessary to carry out numerical integrations in more than 2 dimensions, which is beyond the scope of this work.

In Section 2 we have introduced the models to be employed, along with the topological charge densities providing the lower bounds on the energies. Section 3 is concerned with the imposition of symmetries, *i.e.* stating the axial, azimuthal, intermediate and multi-azimuthal Ansätze. In particular, the energy density functionals of the model, for the dimensions in which numerical solutions will be constructed, are subjected to the spherical, axial and bi-azimuthal symmetries. Subjecting the corresponding topological charge densities to symmetries is carried out in Section 4. Section 5 contains all the numerical results, which verify the assertions presented in the previous Section, 4, concerning the symmetry properties that zero topological charge solutions must have. In Section 6 we summarise our results and extend the discussion of symmetries to beyond the particular simple models employed here.

2 The model and the topological charge

The symmetry breaking models in $D = 3, 4$ and 5 spatial dimensions, to which we refer as Goldstone models, are described by a scalar isovector field ϕ^a , $a = 1, 2, 3$, $a = 1, 2, 3, 4$ and $a = 1, 2, 3, 4, 5$ in each dimension, respectively.

There is such a hierarchy of models [15] that arise from the gauge decoupled limit of the D -dimensional $SO(D)$ gauged Higgs (YMH) model descended from the p -th member of the Yang-Mills (YM) hierarchy on $\mathbb{R}_D \times S^{4p-D}$. Here we have chosen the simplest of these that can accommodate $D = 3, 4, 5$, while satisfying the Derrick scaling requirement for the existence of finite energy solutions. In the present case this is the YMH model that descends from the $p = 3$ -rd member of the YM hierarchy. Our Goldstone model here is the gauge decoupled limit of this YMH system. Using the notation

$$\phi_\mu^a = \partial_i \phi^a \quad , \quad \phi_{\mu\nu}^{ab} = \partial_{[\mu} \phi^a \partial_{\nu]} \phi^b \quad , \quad \phi_{\mu\nu\rho}^{abc} = \partial_{[\mu} \phi^a \partial_{\nu} \phi^b \partial_{\rho]} \phi^c \quad ,$$

with the brackets $[\mu\nu\dots]$ implying total antisymmetrisation, the static energy density functional is

$$\mathcal{E}_{(p=3)} = \lambda_0 (\eta^2 - |\phi^a|^2)^6 + \lambda_1 (\eta^2 - |\phi^b|^2)^4 |\phi_\mu^a|^2 + \lambda_2 (\eta^2 - |\phi^b|^2)^2 |\phi_{\mu\nu}^{ab}|^2 + \lambda_3 |\phi_{\mu\nu\rho}^{abc}|^2 . \quad (1)$$

All the dimensionless constants $\lambda_0, \lambda_1, \lambda_2$ and λ_3 must be positive if the relevant topological lower bounds in each dimension are to be valid. The model (1) is *ad hoc* rather than a dimensionally descended, only insofar as the numerical values of these dimensionless coupling constants, which are otherwise fixed by the descent mechanism, are constrained only to be positive. Of course, any of these constants can also vanish, provided that the absence of the corresponding term in (1) does not violate the Derrick scaling requirement.

The most important feature of models such as (1) is that the order parameter field ϕ^a is a relic of a Higgs field and has the same dimensions (L^{-1}) as a connection, and the finite energy conditions allow the symmetry breaking boundary conditions

$$\lim_{R \rightarrow 0} |\phi^a| = 0 \quad , \quad \lim_{R \rightarrow \infty} |\phi^a| = \eta \quad , \quad (2)$$

R being the radial coordinate in \mathbb{R}^D , this resulting in *monopole*-like asymptotics for our solitons.

The presence of the symmetry breaking potential in (1), multiplying λ_0 , has no quantitative effect on the solutions, so it will be ignored henceforth.

In the next Section, where symmetries will be imposed, we will concentrate only on the terms

$$|\phi_\mu^a|^2 \quad , \quad |\phi_{\mu\nu}^{ab}|^2 \quad , \quad |\phi_{\mu\nu\rho}^{abc}|^2 \quad (3)$$

and will delay the incorporation of the factors $(\eta^2 - |\phi^b|^2)^2$ and $(\eta^2 - |\phi^b|^2)^4$ till the Section on numerics, since imposition of symmetries on these last terms is achieved rather trivially.

The topological charge density bounding the energy density functional from below can be stated simply in terms of Bogomol'nyi inequalities, separately for each dimension $D = 3, 4$ and 5 .

In $D = 3$ the inequality

$$(\eta^2 - |\phi|^2)^2 \left| (\eta^2 - |\phi|^2) \phi_\rho^c - \frac{1}{2!} \varepsilon_{\mu\nu\rho} \varepsilon^{abc} \phi_{\mu\nu}^{ab} \right|^2 \geq 0 \quad (4)$$

leads to the lower bound ¹

$$(\eta^2 - |\phi|^2)^4 |\phi_\mu^a|^2 + \frac{1}{4} (\eta^2 - |\phi|^2)^2 |\phi_{\mu\nu}^{ab}|^2 \geq \varepsilon_{\mu\nu\rho} \varepsilon^{abc} (\eta^2 - |\phi|^2)^3 \phi_\mu \phi_\nu \phi_\rho \equiv \varrho_3. \quad (5)$$

In (4)-(5), we have denoted $|\phi^a|^2$ by $|\phi|^2$.

In $D = 4$ the inequalities

$$\begin{aligned} (\eta^2 - |\phi|^2)^2 \left| \phi_{\mu\nu}^{ab} - \frac{1}{2!} \varepsilon_{\mu\nu\rho\sigma} \varepsilon^{abcd} \phi_{\rho\sigma}^{cd} \right|^2 &\geq 0 \\ \left| (\eta^2 - |\phi|^2)^2 \phi_\rho^c - \frac{1}{3!} \varepsilon_{\mu\nu\rho\sigma} \varepsilon^{abcd} \phi_{\mu\nu\rho}^{abc} \right|^2 &\geq 0 \end{aligned} \quad (6)$$

lead to the lower bound

$$\frac{1}{4} (\eta^2 - |\phi|^2)^4 |\phi_\mu^a|^2 + \frac{1}{2} (\eta^2 - |\phi|^2)^2 |\phi_{\mu\nu}^{ab}|^2 + \frac{1}{4} |\phi_{\mu\nu\rho}^{abc}|^2 \geq \varepsilon_{\mu\nu\rho\sigma} \varepsilon^{abcd} (\eta^2 - |\phi|^2)^2 \phi_\mu \phi_\nu \phi_\rho \phi_\sigma \equiv \varrho_4. \quad (7)$$

In $D = 5$ the inequality

$$\left| (\eta^2 - |\phi|^2) \phi_{\mu\nu}^{ab} - \frac{1}{2^2 3!} \varepsilon_{\mu\nu\rho\sigma\tau} \varepsilon^{abcde} \phi_{\rho\sigma\tau}^{cde} \right|^2 \geq 0$$

leads to the lower bound

$$(\eta^2 - |\phi|^2)^2 |\phi_{\mu\nu}^{ab}|^2 + \frac{1}{4} |\phi_{\mu\nu\rho}^{abc}|^2 \geq \varepsilon_{\mu\nu\rho\sigma\tau} \varepsilon^{abcde} (\eta^2 - |\phi|^2) \phi_\mu \phi_\nu \phi_\rho \phi_\sigma \phi_\tau \equiv \varrho_5. \quad (8)$$

Each of the three topological charge densities ϱ_3 , ϱ_4 and ϱ_5 is a total divergence, which we denote as $\varrho_3 = \partial_\mu \Omega_\mu^{(3)}$, $\varrho_4 = \partial_\mu \Omega_\mu^{(4)}$ and $\varrho_5 = \partial_\mu \Omega_\mu^{(5)}$, respectively, the surface integrals of $\Omega_\mu^{(D)}$ yielding the topological charge in each dimension $D = 3, 4, 5$. In this paper we will refer to the densities $\Omega_\mu^{(D)}$ as *topological currents*. Now these topological charges are simply numerical multiples of the respective winding number densities

$$\varrho_D^{(0)} = \varepsilon_{\mu_1 \mu_2 \dots \mu_D} \varepsilon^{a_1 a_2 \dots a_D} \phi_{\mu_1}^{a_1} \phi_{\mu_2}^{a_2} \dots \phi_{\mu_D}^{a_D} \equiv \partial_{\mu_1} \omega_{\mu_1}^{(D)} \quad (9)$$

which are the surface integrals of the winding number *currents*

$$\omega_{\mu_1}^{(D)} = \varepsilon_{\mu_1 \mu_2 \dots \mu_D} \varepsilon^{a_1 a_2 \dots a_D} \phi_{\mu_1}^{a_1} \phi_{\mu_2}^{a_2} \dots \phi_{\mu_D}^{a_D}. \quad (10)$$

¹Note that the $D = 3$ model employed here is slightly different from that in [11], the latter being the gauge decoupled version of the $p = 2$ YMH model, in contrast to the gauge decoupled version of the $p = 3$ YMH model here.

The topological charges q_3, q_4 and q_5 , which are the volume integrals of the densities ϱ_3, ϱ_4 and ϱ_5 defined in (5), (7) and (8) respectively, are in turn equal to the surface integrals of the topological currents

$$\begin{aligned}
\Omega_\mu^{(3)} &= \varepsilon_{\mu\nu\rho}\varepsilon^{abc}\left[\eta^6 - \frac{9}{5}\eta^4|\phi|^2 + \frac{9}{7}\eta^2(|\phi|^2)^2 - \frac{1}{3}(|\phi|^2)^3\right]\phi^a\phi_\nu^b\phi_\rho^c \\
\Omega_\mu^{(4)} &= \varepsilon_{\mu\nu\rho\sigma}\varepsilon^{abcd}\left[\eta^4 - \frac{4}{3}\eta^2|\phi|^2 + \frac{1}{2}\eta^2(|\phi|^2)^2\right]\phi^a\phi_\nu^b\phi_\rho^c\phi_\sigma^d \\
\Omega_\mu^{(5)} &= \varepsilon_{\mu\nu\rho\sigma\tau}\varepsilon^{abcde}\left[\eta^2 - \frac{5}{7}\eta^2|\phi|^2\right]\phi^a\phi_\nu^b\phi_\rho^c\phi_\sigma^d\phi_\tau^e.
\end{aligned} \tag{11}$$

It is now obvious, in light of the asymptotic boundary value in (2), that q_3, q_4 and q_5 are multiples of the winding numbers, namely the surface integrals of the currents (10), with the numbers $\frac{16}{105}, \frac{1}{6}$ and $\frac{1}{7}$, respectively.

3 Imposition of symmetries

This section is divided into four subsections, in each of which the three building blocks in (3) will be subjected to spherical, axial, azimuthal, and in 4 dimensions only, the bi-azimuthal symmetries respectively. We shall also state the tri-azimuthal Ansatz, only in 6 dimensions, but will not display the building blocks (3) subject to it because in 6 dimensions the Derrick scaling requires an *octic* term beyond these, whose numerical pursuit is beyond the scope of this work. The symmetry breaking selfinteraction potential $(\eta^2 - |\phi^a|^2)^6$ will be ignored, instead the boundary condition (2) it would enforce will be imposed directly.

Imposition of symmetry is the first step in the construction of zero topological charge solutions, leading to the second step of selecting the requisite boundary conditions to achieve this aim. In this section, we impose the symmetries on the energy density functional (1) whose second order equations will be integrated numerically in Section 5, deferring the task of imposing symmetries on the topological charge densities (9) and their currents (10) to the next section, 4. There, the most important task of selecting the requisite boundary conditions will be made.

Before stating the Ansätze pertaining to the various symmetries to be imposed on the scalar field ϕ^a describing the model (1), we introduce the coordinates to be employed in each case. Next to spherical symmetry, the strongest symmetry that we will impose is the *axial* symmetry, sometimes described also as *cylindric* symmetry. This involves imposition of rotational symmetry in a \mathbb{R}^{D-1} subspace of the full space \mathbb{R}^D . The weakest symmetry is the *azimuthal* one, which involves imposition of rotational symmetry in a \mathbb{R}^2 subspace of \mathbb{R}^D . Then there are all the *intermediate* symmetries involving imposition of rotational symmetry in a \mathbb{R}^n subspace of \mathbb{R}^D , with $D - 2 \geq n \geq 3$. As we restrict to $D = 5$, the only relevant values of n are $n = 3$ and 4. In addition, we will employ *multi-azimuthal* symmetries, each one of its constituent azimuthal symmetries being imposed on distinct planes in \mathbb{R}^D . Since we will restrict to $D = 6$, our attention will be restricted to the *bi-azimuthal* and *tri-azimuthal* cases only. The coordinates are parametrised as follows.

Axial coordinates:

In this case we label the coordinate on \mathbb{R}^D as follows,

$$x_\mu = (x_i, x_D) \quad , \quad i = 1, 2, \dots, D-1 \quad , \quad |x_i|^2 = r^2 \quad , \quad R^2 = r^2 + x_D^2, \quad (12)$$

so that

$$r = R \sin \theta_1 \quad , \quad x_D = R \cos \theta_1, \quad (13)$$

where θ_1 is the leading polar angle in each dimension, parametrised by the spherical polar angles $(\theta_1, \theta_2, \dots, \theta_{D-3}, \theta_{D-2}, \varphi)$, φ being the azimuthal angle (with $0 \leq \varphi \leq 2\pi$, $0 \leq \theta_i \leq \pi$) Our definition of axial symmetry amounts to spherical symmetry in the $D-1$ dimensional subspace, as for example in [12].

Azimuthal coordinates:

Imposing azimuthal symmetry in the $x_i = (x_1, x_2)$ plane, leaves the dependence of the fields on the coordinates $x_I = (x_3, x_4, \dots, x_D)$ unrestricted. In practice however, we will restrict to the $D=4$ case only for reasons explained in Section 4 below. The labeling we will employ is

$$x_\mu = (x_i, x_I) \quad , \quad i = 1, 2 \quad , \quad I = 3, 4 \quad , \quad |x_i|^2 = \rho^2 \quad , \quad R^2 = \rho^2 + |x_I|^2, \quad (14)$$

so that

$$\rho = R \sin \theta_1 \sin \theta_2 \quad , \quad x_3 = R \sin \theta_1 \cos \theta_2 \quad , \quad x_4 = R \cos \theta_1, \quad (15)$$

or

$$\rho = r \sin \theta_2 \quad , \quad x_3 = z = r \cos \theta_2 \quad , \quad x_4 = t. \quad (16)$$

Intermediate coordinates:

In $D=5$ the only *intermediate* possibility is $n=3$, and we label the coordinate as

$$x_\mu = (x_i, x_4, x_5) \equiv (x_i, s, t) \quad , \quad i = 1, 2, 3 \quad , \quad |x_i|^2 = r^2 \quad , \quad R^2 = r^2 + s^2 + t^2, \quad (17)$$

so that

$$r = R \sin \theta_1 \sin \theta_2 \quad , \quad s = R \sin \theta_1 \cos \theta_2 \quad , \quad t = R \cos \theta_1, \quad (18)$$

in an angular parametrisation $(\theta_1, \theta_2, \theta_3, \varphi)$, with polar angles ranging from 0 to π , φ being the azimuthal angle ranging from 0 to 2π . The notation

$$\hat{x}_i = (\sin \theta_3 \cos \varphi, \sin \theta_3 \sin \varphi, \cos \theta_3) \quad (19)$$

will be employed below.

In $D=6$ both $n=3$ and $n=4$ are possible, but the second leads to a 4 dimensional effective system which is superfluous for our purposes here. Hence we restrict to $n=3$ and label the coordinate as

$$x_\mu = (x_i, x_5, x_6) \equiv (x_i, s, t) \quad , \quad i = 1, 2, 3, 4 \quad , \quad |x_i|^2 = r^2 \quad , \quad R^2 = r^2 + s^2 + t^2, \quad (20)$$

so that (r, s, t) are parametrised exactly as in (18) in an angular parametrisation $(\theta_1, \theta_2, \theta_3, \theta_4, \varphi)$. The notation

$$\hat{x}_i = (\sin \theta_3 \sin \theta_4 \cos \varphi, \sin \theta_3 \sin \theta_4 \sin \varphi, \sin \theta_3 \cos \theta_4, \cos \theta_3) \quad (21)$$

being employed for this case below.

Bi-azimuthal coordinates:

In this case we will restrict our attention to $D = 4$ and $D = 5$. (Bi-azimuthal symmetry in $D = 6$ would lead to four dimensional residual subsystems, which are superfluous for our purposes here.) In the first case we will subject the components of the energy density functional (3) to the symmetry implied by the Ansatz, while in the second, we will only state the Ansatz since no solutions will be constructed subsequently in that case.

In $D = 4$ we impose a second azimuthal symmetry in (14), in the $x_I = (x_3, x_4)$, plane, denoting the radial variable in the (x, y) and (z, t) planes with $\rho = \sqrt{x^2 + y^2} = \sqrt{|x_i|^2}$ and $\sigma = \sqrt{z^2 + t^2} = \sqrt{|x_I|^2}$. In this case, we will parametrise \mathbb{R}^4 as

$$\begin{aligned} x_i &= (R \sin \psi) \hat{x}_i \equiv \rho \hat{x}_i \quad , \quad \hat{x}_i = (\cos \varphi_1, \sin \varphi_1) \\ x_I &= (R \cos \psi) \hat{x}_I \equiv \sigma \hat{x}_I \quad , \quad \hat{x}_I = (\cos \varphi_2, \sin \varphi_2) \end{aligned} \quad (22)$$

where $R^2 = |x_i|^2 + |x_I|^2 = |x_\mu|^2$, with $0 \leq \psi \leq \frac{\pi}{2}$, $0 \leq \varphi_1 \leq 2\pi$ and $0 \leq \varphi_2 \leq 2\pi$. While the two angles (φ_1, φ_2) are azimuthal angles, the angle θ here is not a polar angle as its range is one half of that of a polar angle. We shall refer to such angles as semi-polar henceforth.

In $D = 5$, \mathbb{R}^5 is parametrised as

$$x_i = (R \sin \theta \sin \psi) \hat{x}_i \equiv r \hat{x}_i \quad , \quad \hat{x}_i = (\cos \varphi_1, \sin \varphi_1) \quad (23)$$

$$\begin{aligned} x_I &= (R \sin \theta \cos \psi) \hat{x}_I \equiv s \hat{x}_I \quad , \quad \hat{x}_I = (\cos \varphi_2, \sin \varphi_2) \\ x_5 &= R \cos \theta \equiv t \end{aligned} \quad (24)$$

where $R^2 = r^2 + s^2 + t^2$, and $0 \leq \theta \leq \pi$ and $0 \leq \psi \leq \frac{\pi}{2}$. In (23)-(24), θ is a polar angle and ψ a semi-polar angle. We denote polar angles by θ and semi-polar angles by ψ henceforth. All azimuthal angles are likewise denoted by φ .

Tri-azimuthal coordinates:

Here we restrict our attention to $D = 6$ only for reasons explained already. Extending the labeling (22) of \mathbb{R}^4 to that of \mathbb{R}^6 , with $\rho = \sqrt{x_1^2 + x_2^2} = \sqrt{|x_{i_1}|^2}$, $i_1 = 1, 2$, $\sigma = \sqrt{x_3^2 + x_4^2} = \sqrt{|x_{i_2}|^2}$, $i_2 = 3, 4$, and $\tau = \sqrt{x_5^2 + x_6^2} = \sqrt{|x_{i_3}|^2}$, $i_3 = 5, 6$, by

$$\begin{aligned} x_{i_1} &= (R \sin \psi_1 \sin \psi_2) \hat{x}_{i_1} \equiv \rho \hat{x}_{i_1} \quad , \quad \hat{x}_{i_1} = (\cos \varphi_1, \sin \varphi_1) \\ x_{i_2} &= (R \sin \psi_1 \cos \psi_2) \hat{x}_{i_2} \equiv \sigma \hat{x}_{i_2} \quad , \quad \hat{x}_{i_2} = (\cos \varphi_2, \sin \varphi_2) \\ x_{i_3} &= (R \cos \psi_1) \hat{x}_{i_3} \equiv \tau \hat{x}_{i_3} \quad , \quad \hat{x}_{i_3} = (\cos \varphi_3, \sin \varphi_3) \end{aligned} \quad (25)$$

where $R^2 = |x_{i_1}|^2 + |x_{i_2}|^2 + |x_{i_3}|^2 = |x_\mu|^2$, with $0 \leq \psi_1 \leq \frac{\pi}{2}$, $0 \leq \psi_2 \leq \frac{\pi}{2}$, and with the three azimuthal angles $0 \leq \varphi_1 \leq 2\pi$, $0 \leq \varphi_2 \leq 2\pi$ and $0 \leq \varphi_3 \leq 2\pi$.

3.1 Spherical symmetry

The spherically symmetric Ansatz for the scalar field ϕ^a in D dimensions is

$$\phi^a = \eta Q(R) \hat{x}^a \quad , \quad \hat{x}^a = \frac{x^a}{R} \quad , \quad (26)$$

resulting in the reduced building blocks (3)

$$\begin{aligned} |\phi_\mu^a|^2 &= Q_R^2 + (D-1) \left(\frac{Q}{R}\right)^2 \\ |\phi_{\mu\nu}^{ab}|^2 &= 2(D-1) \left(\frac{Q}{R}\right)^2 \left[2Q_R^2 + (D-2) \left(\frac{Q}{R}\right)^2 \right] \\ |\phi_{\mu\nu\rho}^{abc}|^2 &= 6(D-1)(D-2) \left(\frac{Q}{R}\right)^4 \left[3Q_R^2 + (D-3) \left(\frac{Q}{R}\right)^2 \right] \end{aligned} \quad (27)$$

where we have used the notation $Q_R = \frac{\partial Q}{\partial R}$.

3.2 Axial symmetry

The axially symmetric Ansatz for the scalar field $\phi^a = (\phi^\alpha, \phi^D)$ in $D \geq 4$ dimensions, with the index $\alpha = 1, 2, \dots, D-1$ is

$$\phi^\alpha = \eta H(r, x_D) \hat{x}^\alpha \quad , \quad \phi^D = \eta G(r, x_D) \quad , \quad \hat{x}^\alpha = \frac{x^\alpha}{r} \quad , \quad (28)$$

using the labeling (12) of the coordinates.

There is a very important exception in the $D = 3$ case of (28), where imposition of axial symmetry on the field $\phi^a = (\phi^A, \phi^3)$, $A = 1, 2$, is tantamount to imposing azimuthal symmetry. The axially symmetric Ansatz in $D = 3$ is

$$\phi^A = \eta H(r, x_3) n^A \quad , \quad \phi^3 = \eta G(r, x_3) \quad , \quad n^A = \begin{bmatrix} \cos n\varphi \\ \sin n\varphi \end{bmatrix} \quad , \quad (29)$$

$n = 1, 2, 3, \dots$ being the azimuthal vortex number.

The result of substituting (12) in (3) is

$$\begin{aligned} |\phi_\mu^a|^2 &= (H_r^2 + G_r^2 + H_D^2 + G_D^2) + (D-2) \left(\frac{H}{r}\right)^2 \quad , \\ \frac{1}{2} |\phi_{\mu\nu}^{ab}|^2 &= 2(H_{[r} G_{D]})^2 + (D-2) \left(\frac{H}{r}\right)^2 \left[2(H_r^2 + G_r^2 + H_D^2 + G_D^2) + (D-3) \left(\frac{H}{r}\right)^2 \right] \quad , \\ \frac{1}{6} |\phi_{\mu\nu\rho}^{abc}|^2 &= (D-2) \left(\frac{H}{r}\right)^2 \left\{ 6(H_{[r} G_{D]})^2 + \right. \\ &\quad \left. + (D-3) \left(\frac{H}{r}\right)^2 \left[3(H_r^2 + G_r^2 + H_D^2 + G_D^2) + (D-4) \left(\frac{H}{r}\right)^2 \right] \right\} \quad , \end{aligned} \quad (30)$$

where we have used the notation $H_r = \frac{\partial H}{\partial r}$, $H_D = \frac{\partial H}{\partial x_D}$, and $H_{[r} G_{D]} = (H_r G_D - H_D G_r)$.

The spherically symmetric limit (27) of (31) follows immediately from (13), by the replacements

$$H(r, x_D) = Q(R) \sin \theta_{D-2} \quad , \quad G(r, x_D) = Q(R) \cos \theta_{D-2} ,$$

with $R^2 = r^2 + x_D^2$, and using

$$\partial_r = \sin \theta_{D-2} \partial_R + \frac{\cos \theta_{D-2}}{R} \partial_{\theta_{D-2}} \quad , \quad \partial_D = \cos \theta_{D-2} \partial_R - \frac{\sin \theta_{D-2}}{R} \partial_{\theta_{D-2}} .$$

3.3 Azimuthal symmetry

This subsection is concerned with the imposition of azimuthal symmetry in a D dimensional system, resulting in a $D - 1$ dimensional residual subsystem. As such, it does not lead to a boundary value problem which can be tackled numerically in a practical way. It should thus be viewed as a first step towards the imposition of bi-azimuthal symmetry in the $D = 2 + 2 = 4$ case presented in the next subsection.

Imposing azimuthal symmetry in the $x_i = (x_1, x_2)$ subspace (plane) of $x_\mu = (x_i, x_I)$, $I = 3, 4, \dots, D$, and labeling the scalar field as $\phi^a = (\phi^A, \phi^{A'})$, $A = 1, 2$ and $A' = 3, 4, \dots, D$, the components ϕ^A are restricted by the Ansatz

$$\phi^A = \chi^{D-1}(x_I, \rho) = h(\rho, x_I) n^A \quad , \quad n^A = (\cos n\varphi, \sin n\varphi) \quad , \quad \rho^2 = |x_i|^2 = x^2 + y^2, \quad (31)$$

while the $D-2$ components $\phi^{A'} = \phi^{A'}(\rho, x_I)$ retain their dependence on the $D-2$ coordinates x_I .

The result of enforcing the Ansatz (31) is most compactly expressed by employing the coordinate $x_M = (x_I, \rho)$, and by labeling the residual field as $\chi^\alpha = (\chi^{A'}, \chi^{D-1}) \equiv (\phi^{A'}, h)$, with the new index running over $\alpha = A', D - 1$. In this notation we have

$$\begin{aligned} |\phi_\mu^a|^2 &= \left(\frac{n\chi^{D-1}}{\rho} \right)^2 + |\partial_M \chi^\alpha|^2 \\ \frac{1}{2} |\phi_{\mu\nu}^{ab}|^2 &= 4 \left(\frac{n\chi^{D-1}}{\rho} \right)^2 |\partial_M \chi^\alpha|^2 + |\partial_{[M} \chi^\alpha \partial_{N]} \chi^\beta|^2 \\ \frac{1}{6} |\phi_{\mu\nu\rho}^{abc}|^2 &= \frac{5}{2} \left(\frac{n\chi^{D-1}}{\rho} \right)^2 |\partial_M \chi^\alpha|^2 + |\partial_{[M} \chi^\alpha \partial_{N]} \chi^\beta|^2 + \frac{1}{6} |\partial_{[M} \chi^\alpha \partial_N \chi^\beta \partial_{R]} \chi^\gamma|^2 \end{aligned} \quad (32)$$

In the case of interest here, namely for $D = 4$, $x_\mu = (x_i, x_I)$, with $i = 1, 2 = x, y$ and $I = 3, 4 = z, t$, the azimuthally symmetric Ansatz (31) now becomes

$$\phi^A = \chi^3(x_I, \rho) = h(\rho, z, t) n^A \quad , \quad \phi^{A'} = \chi^{A'}(x_I, \rho) = \begin{bmatrix} f(\rho, z, t) \\ g(\rho, z, t) \end{bmatrix}, \quad (33)$$

resulting in the residual 3 dimensional system with coordinates $x_M = (z, t, \rho)$ being given by (32) with $\chi^{D-1} = \chi^3 \equiv h$.

The axially symmetric limit (31) of (32) follows immediately from (15), by the replacements

$$h(z, t, \rho) = H(r, t) \sin \theta_1 \quad , \quad f(z, t, \rho) = H(r, t) \cos \theta_1 \quad , \quad g(z, t, \rho) = G(r, t) \quad ,$$

with $r^2 = \rho^2 + z^2$, and using

$$\partial_\rho = \sin \theta_1 \partial_r + \frac{\cos \theta_1}{r} \partial_{\theta_1} \quad , \quad \partial_z = \cos \theta_1 \partial_r - \frac{\sin \theta_1}{r} \partial_{\theta_1} \quad .$$

3.4 Intermediate symmetries

The symmetries to be considered here are rotational symmetry in the \mathbb{R}^3 subspace of \mathbb{R}^5 (for $D = 5$), and the \mathbb{R}^4 subspace of \mathbb{R}^6 (for $D = 6$). (Rotational symmetry in the \mathbb{R}^3 subspace of \mathbb{R}^6 would be superfluous since that would lead to a four dimensional effective system.)

For $D = 5$, the intermediate symmetric Ansatz for the field $\phi^a = (\phi^\alpha, \phi^4, \phi^5)$ is

$$\phi^\alpha = \eta h(r, s, t) \hat{x}^\alpha \quad , \quad \phi^4 = \eta g(r, s, t) \quad , \quad \phi^5 = \eta f(r, s, t) \quad (34)$$

using the notation of (17)-(19).

The intermediate symmetric Ansatz for the field $\phi^a = (\phi^\alpha, \phi^5, \phi^6)$ for $D = 6$ is

$$\phi^\alpha = \eta h(r, s, t) \hat{x}^\alpha \quad , \quad \phi^5 = \eta g(r, s, t) \quad , \quad \phi^6 = \eta f(r, s, t) \quad (35)$$

which looks formally identical to (34), but now the coordinates being read from (20)-(21).

In both cases the system reduces to a three dimensional effective subsystems, for which numerical constructions are outside the scope of this work. Hence we do not present the result of symmetry imposition on the energy density functionals (3).

3.5 Bi-azimuthal symmetry

Our considerations in this subsection cover two cases, namely to state the bi-azimuthal Ansätze in $D = 4$ and $D = 5$. The residual subsystem in each case is two dimensional and three dimensional, respectively. In the first case we will construct the solutions numerically, so the Ansatz will be imposed on the energy density functional, while in the second we will limit ourselves to stating the Ansatz.

Bi-azimuthal symmetry in $D = 4$:

In the $D = 4$ case, using the notation (22) for the coordinates and using the same notation (31) as in subsection **3.3**, $\phi^a = (\phi^A, \phi^{A'})$, the bi-azimuthally symmetric Ansatz is

$$\begin{aligned} \phi^A &= \eta h(\rho, \sigma) n_1^A \quad , \quad n_1^A = (\cos n_1 \varphi_1, \sin n_1 \varphi_1) \quad , \\ \phi^{A'} &= \eta g(\rho, \sigma) n_2^{A'} \quad , \quad n_2^{A'} = (\cos n_2 \varphi_2, \sin n_2 \varphi_2) \quad , \end{aligned} \quad (36)$$

where n_1 and n_2 are the respective vorticities in the two planes.

In fact the Ansatz (36) results in the first stage from the imposition of azimuthal symmetry (31) in $D = 4$, with the residual fields $\chi^\alpha = (\phi^{A'}, h)$, and then imposing a second stage

of azimuthal symmetry on the triplet χ^α . Concerning the imposition of the second stage of azimuthal symmetry, we point out that the densities (32) resulting from the first stage do not exhibit a global $SO(D-1)$ invariance, although the original densities (3) are invariant under a global $SO(D)$ ². We have verified that the second stage results a consistent reduction, even though the reduced system after the first stage did not possess a global invariance.

Imposition of bi-azimuthal symmetry enables a 2 dimensional boundary value problem, to be tackled numerically in the next section, so we list the resulting densities (3)

$$\begin{aligned} |\phi_\mu^a|^2 &= \left[\left(\frac{n_1 h}{\rho} \right)^2 + \left(\frac{n_2 g}{\sigma} \right)^2 \right] + (h_\rho^2 + g_\rho^2 + h_\sigma^2 + g_\sigma^2) \\ \frac{1}{2!^2} |\phi_{\mu\nu}^{ab}|^2 &= \left(\frac{n_1 h}{\rho} \right)^2 \left(\frac{n_2 g}{\sigma} \right)^2 + \left[\left(\frac{n_1 h}{\rho} \right)^2 + \left(\frac{n_2 g}{\sigma} \right)^2 \right] (h_\rho^2 + g_\rho^2 + h_\sigma^2 + g_\sigma^2) + (h_{[\rho} g_{\sigma]})^2 \\ \frac{1}{3!^2} |\phi_{\mu\nu\rho}^{abc}|^2 &= \left(\frac{n_1 h}{\rho} \right)^2 \left(\frac{n_2 g}{\sigma} \right)^2 (h_\rho^2 + g_\rho^2 + h_\sigma^2 + g_\sigma^2) + \left[\left(\frac{n_1 h}{\rho} \right)^2 + \left(\frac{n_2 g}{\sigma} \right)^2 \right] (h_{[\rho} g_{\sigma]})^2 \end{aligned} \quad (37)$$

where we have used the notation $h_\rho = \frac{\partial h}{\partial \rho}$, $H_\sigma = \frac{\partial h}{\partial \sigma}$, and $g_{[\rho} g_{\sigma]} = (h_\rho g_\sigma - g_\rho h_\sigma)$ as in (31).

In terms of the coordinates $\rho = R \sin \theta$, $\sigma = R \cos \theta$ defined by (22), the spherically symmetric limit (31) of (37) follows immediately from by the replacements

$$h(\rho, \sigma) = Q(R) \sin \theta \quad , \quad g(\rho, \sigma) = Q(R) \cos \theta \quad ,$$

and using

$$\partial_\rho = \sin \theta \partial_R + \frac{\cos \theta}{R} \partial_\theta \quad , \quad \partial_\sigma = \cos \theta \partial_R - \frac{\sin \theta}{R} \partial_\theta .$$

This limit will be exploited in the numerical constructions.

Bi-azimuthal symmetry in $D = 5$:

Here, the residual system being three dimensional, we simply state the Ansatz

$$\phi^A = \eta h(r, s, t) n_1^A \quad , \quad n_1^A = (\cos n_1 \varphi_1, \sin n_1 \varphi_1) \quad , \quad (38)$$

$$\phi^{A'} = \eta g(r, s, t) n_2^{A'} \quad , \quad n_2^{A'} = (\cos n_2 \varphi_2, \sin n_2 \varphi_2) \quad , \quad (39)$$

$$\phi^5 = \eta f(r, s, t) \quad , \quad (40)$$

in the notation of (23)-(24).

3.6 Tri-azimuthal symmetry

As noted at the start of this section, we shall simply state the Ansatz here, for 6 dimensions only, without imposing the symmetry on the energy density building blocks (3). Then in the next section we will use this to calculate the topological charge of the putative solutions in

²This is in contrast to that of a YM system, where the local gauge group does, under azimuthal symmetry imposition, reduce to an effective YM-Higgs system exhibiting a broken local gauge invariance [10].

6 dimensions, which are not constructed numerically here. The tri-azimuthally symmetric Ansatz for $\phi^a = (\phi^{A_1}, \phi^{A_2}, \phi^{A_3})$, $A_1 = 1, 2$, $A_2 = 13, 4$, $A_3 = 5, 6$

$$\begin{aligned}\phi^{A_1} &= h(\rho, \sigma, \tau) n_1^{A_1} \quad , \quad n_1^{A_1} = (\cos n_1 \varphi_1, \sin n_1 \varphi_1) \\ \phi^{A_2} &= g(\rho, \sigma, \tau) n_2^{A_2} \quad , \quad n_2^{A_2} = (\cos n_2 \varphi_2, \sin n_2 \varphi_2) \\ \phi^{A_3} &= f(\rho, \sigma, \tau) n_2^{A_3} \quad , \quad n_2^{A_3} = (\cos n_3 \varphi_2, \sin n_3 \varphi_2)\end{aligned}\tag{41}$$

where n_1 , n_2 and n_3 are the respective vorticities in the three planes (x_1, x_2) , (x_3, x_4) and (x_5, x_6) .

4 Topological charges and boundary values

In this Section, we present in detail the topological charges resulting from the various types of boundary values of the scalar field. This is relevant when subjecting the fields to axial, azimuthal intermediate bi-azimuthal and tri-azimuthal symmetries in turn. Under each (symmetry) heading, we will calculate the topological charges in all dimensions D for which the residual subsystem is at most **three** dimensional. This will cover the generic cases, all further examples being superfluous. Subject to axial symmetry, we consider the cases $D = 3, 4, 5, 6$. Subject to azimuthal symmetry, we cover only $D = 4$. Subject to intermediate symmetry, we take the cases $D = 5, 6$. For configurations with bi-azimuthal symmetry, we cover $D = 4, 5$. Subject to tri-azimuthal symmetry, we cover the only possible case $D = 6$.

As explained at the end of Section 2, it is sufficient to calculate the winding numbers since the topological charges are simply numerical multiples of the latter. Up to angular volume normalisations N_D , these are the surface integrals of the currents (10), hence what we need to calculate are the asymptotic values of the quantities $\hat{x}_\mu \omega_\mu^{(D)}$ to enable us to evaluate the surface integrals

$$I_D = \int \hat{x}_\mu \omega_\mu^{(D)} \Big|_{R=\infty} R^{D-1} d\Omega(\theta_{D-2}, \theta_{D-3}, \dots, \theta_1, \varphi),\tag{42}$$

\hat{x}_μ being the unit vector, and $d\Omega(\theta_{D-2}, \theta_{D-3}, \dots, \theta_1, \varphi)$ the angular volume element, in \mathbb{R}^D .

Here, we will evaluate the angular integrals (42), (a) subject to axial symmetry for $D = 3, 4, 5, 6$, (b) subject to azimuthal symmetry for $D = 4$, and (c) subject to bi-azimuthal symmetry for $D = 4$.

4.1 Axial symmetry

In the case of axially symmetric fields, we will impose the following asymptotic boundary values on the functions $H(r, x_D)$ and $G(r, x_D)$ defined in (28) for $D \geq 4$, and in (29) for $D = 3$

$$\begin{aligned}\lim_{R \rightarrow \infty} H(r, x_D) &= \sin m \theta_1 \\ \lim_{R \rightarrow \infty} G(r, x_D) &= \cos m \theta_1 \quad , \quad m = 1, 2, 3, \dots\end{aligned}\tag{43}$$

The topological charges of the axially symmetric models in $D = 3, 4, 5$ are given by the (volume) integrals

$$q_D = D! \Omega_{D-1} \int H^{D-2} (G_R H_{\theta_1} - H_R G_{\theta_1}) dR d\theta_1, = I_D$$

$\Omega_{D-1} = 2\pi, 2\pi^2, \frac{8\pi^2}{3}$, being the angular volumes in each of these dimensions, respectively.

The surface integrals (42) can be evaluated analytically. In the axially symmetric cases at hand, where the corresponding volume integrals are two dimensional, these become contour integrals in the positive half plane $r[0, \infty)$, $x_D(-\infty, +\infty)$ by virtue of Stokes' theorem. Now the line integral along the x_D axis does not contribute since analyticity requires that $H(\theta_1 = 0) = H(\theta_1 = \pi) = 0$, so the only contribution comes from the infinite semicircle, thus reducing (42) to the following one dimensional angular integrals

$$I_D^{\text{axial}} = D! \Omega_D \int H^{D-2} (G H_{\theta_1} - H G_{\theta_1}) \Big|_{R=\infty} d\theta_1, \quad (44)$$

with the exception of the $D = 3$ case where axial symmetry coincides with azimuthal symmetry, when

$$I_3 = 2! 2\pi n \int H (G H_{\theta} - H G_{\theta}) \Big|_{R=\infty} d\theta. \quad (45)$$

Subject to the axially symmetric boundary values (43), the integrals (45) and (44) for $D = 3$ and $D = 4, 5, 6$ are evaluated as

$$I_3^{\text{ax}} = 4 \eta^3 \pi n [1 - (-1)^m] \quad (46)$$

$$I_4^{\text{ax}} = 12 \eta^4 \pi^2 m \quad (47)$$

$$I_5^{\text{ax}} = 32 \eta^5 \pi^2 [1 - (-1)^m] \quad (48)$$

$$I_6^{\text{ax}} = 5! \eta^6 \pi^3 m. \quad (49)$$

We now see from (46) and (48), that in odd D dimensions axially symmetric fields are capable of supporting *zero topological charge* solutions describing an even number m of soliton–antisoliton energy/charge concentrations on the x_D axis, as well as *unit topological charge* solutions describing chains [9] of odd number m of such nodes on the symmetry axis³. We see by contrast from (47) and (49), that in even D dimensions axially symmetric fields are **not** capable of supporting *zero topological charge* solutions. They describe only multisoliton solutions of topological charges m , the concentrations of charge/energy being located on the x_D axis. (These are the analogues of Witten's axially symmetric instantons [12].) Our numerical solutions in the next Section will bear out these conclusions.

Having described candidates for *zero topological charge* solutions in odd dimensions, we proceed to explore prescriptions whereby such solutions in even D dimensions can also be constructed. This is possible only if less stringent symmetry than axial symmetry is imposed on the system, and below we describe two such distinct prescriptions in $D = 4$, employing in turn azimuthal and bi-azimuthal symmetries, and one such prescription in $D = 6$ employing tri-azimuthal symmetry.

³subsequent to the construction of zero charge monopole–antimonopole pairs [?, 8], such charge chains of monopoles and antimonopoles of *unit* topological charge were constructed in [9].

4.2 Azimuthal symmetry

In the case of azimuthal symmetry in $D = 4$, the asymptotic boundary values to be imposed on the functions $h(\rho, z, t)$, $f(\rho, z, t)$ and $g(\rho, z, t)$ defined in (33) are

$$\begin{aligned}\lim_{R \rightarrow \infty} h(\rho, z, t) &= \sin m_1 \theta_1 \sin m_2 \theta_2 \\ \lim_{R \rightarrow \infty} f(\rho, z, t) &= \sin m_1 \theta_1 \cos m_2 \theta_2 \\ \lim_{R \rightarrow \infty} g(\rho, z, t) &= \cos m_1 \theta_1 \quad , \quad m_1, m_2 = 1, 2, 3, \dots\end{aligned}\tag{50}$$

We note here that the asymptotic axially symmetric boundary values are described by one integer m for $D \geq 4$ and two integers (m, n) for $D = 3$, while those for the azimuthal boundary values for $D = 4$ are given in terms of the triple of integers (m_1, m_2, n) .

Substituting azimuthal Ansatz (31) in (42) for $D = 4$, and using the analyticity requirement that $h(r, t)$ vanishes on the t -axis, this reduces to the two dimensional angular integral

$$I_4^{\text{az}} = 4! n \int h [h (f_{\theta_2} g_{\theta_1} - f_{\theta_1} g_{\theta_2}) + f (g_{\theta_2} h_{\theta_1} - h_{\theta_1} h_{\theta_2}) + g (h_{\theta_2} f_{\theta_1} - g_{\theta_1} f_{\theta_2})] d\theta_1 d\theta_2, \tag{51}$$

which can readily be evaluated subject to the boundary conditions (50) to yield

$$I_4^{\text{azim}} = 12 \eta^4 \pi^2 m_1 n [1 - (-1)^{m_2}]. \tag{52}$$

This accommodates both multi-soliton (for *odd* m_2) and zero topological charge (for *even* m_2) solutions, labeled by the triple of integers (m_1, m_2, n) . Unfortunately the numerical solution the corresponding field equations involves three dimensional integration, which task is beyond the scope of the present work.

4.3 Intermediate symmetries

In both the $D = 5$ and $D = 6$ cases discussed in section 3.4 above, the asymptotic behaviours consistent with finite energy are both stated formally as

$$\begin{aligned}\lim_{R \rightarrow \infty} h(r, s, t) &= \sin m_1 \theta_1 \sin m_2 \theta_2 \\ \lim_{R \rightarrow \infty} g(r, s, t) &= \sin m_1 \theta_1 \cos m_2 \theta_2 \\ \lim_{R \rightarrow \infty} f(r, s, t) &= \cos m_1 \theta_1 \quad , \quad m_1, m_2 = 1, 2, 3, \dots\end{aligned}\tag{53}$$

augmented by the analyticity condition $h(r = 0) = 0$, which is crucial in the evaluation of the surface integrals. In both the $D = 5$ and $D = 6$ here, these follow from three dimensional volume integrals which are formally identical. Up to numerical factors, these are expressed as

$$\begin{aligned}I_{5,6}^{\text{int}} &\sim \eta^{5,6} (\pi)^{2,3} m_1 m_2 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \partial_\mu \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C dr ds dt \\ &= \eta^{5,6} (\pi)^{2,3} m_1 m_2 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C dS_\mu, \end{aligned}\tag{54}$$

where we have used the notation $x_\mu = (r, s, t)$, and, the triplet function Ξ^A , $A = 1, 2, 3$ in the two cases is defined in terms of the functions (h, g, f) as

$$\Xi^A = ((h)^3, g, f) \quad \text{and} \quad \Xi^A = ((h)^4, g, f) ,$$

respectively. The nonvanishing contributions to the surface integral(s) (54) come from the upper hemisphere.

The values of the respective surface integrals in $D = 5, 6$ are calculated to be

$$I_5^{\text{inter}} = \frac{5 \cdot 2^6}{3^2} \eta^5 \pi^2 m_2 [1 - (-1)^{m_1}] \quad (55)$$

$$I_6^{\text{inter}} = 15 \eta^6 \pi^3 m_1 [1 - (-1)^{m_2}] , \quad (56)$$

thus, by relaxing axial symmetry and imposing a weaker symmetry, it is possible to support both *multisolitons* of arbitrary topological charges, and, *soliton-antisolitons* chains, with *zero* and *nonzero* topological charges in *all dimensions*. Unfortunately the simplest such examples result in three dimensional boundary value problems, which is at present technically too hard a task to perform. The situation is the same in the azimuthal case in $D = 4$ above.

4.4 Bi-azimuthal symmetry

Bi-azimuthal symmetry will be applied in $D = 4$ and $D = 5$, each resulting in a two and a three dimensional subsystems, respectively.

$D = 4 = 2 + 2$

In this case the fields are described by the bi-azimuthal Ansatz (36). The asymptotic behaviours of the functions h and g in (36) are taken to be

$$\lim_{R \rightarrow \infty} h = \sin m\psi , \quad \lim_{R \rightarrow \infty} g = \cos m\psi . \quad (57)$$

The topological charge in this case is

$$\begin{aligned} I_4^{\text{bi-azim}} &= \eta^4 3! (2\pi)^2 n_1 n_2 \int \varepsilon_{\mu\nu} \varepsilon^{AB} \partial_\mu \Xi^A \partial_\nu \Xi^B d\rho d\sigma \\ &= \eta^4 3! (2\pi)^2 n_1 n_2 \int (\varepsilon^{AB} \Xi^A \partial_\mu \Xi^B) ds_\mu \end{aligned} \quad (58)$$

where we have used the notation $x_\mu = (\rho, \sigma)$, and $\Xi^A = ((h)^2, (g)^2)$.

Using the analyticity conditions $h(\psi = 0) = 0$ and $g(\psi = \frac{\pi}{2}) = 0$ leads to the vanishing of the line integrals on the ρ and the σ axes, the non vanishing contribution coming from the infinite quarter circle contour, readily evaluated to yield

$$I_4^{\text{bi-azim}} = \eta^4 2 \pi^2 n_1 n_2 [1 - (-1)^m] , \quad (59)$$

which supports both multisolitons and zero charge soliton-antisolitons.

$$\underline{D = 5 = 2 + 2 + 1}$$

In this case the fields are described by the bi-azimuthal Ansatz (39). The asymptotic behaviours of the functions h and g and f in (39) are taken to be

$$\lim_{R \rightarrow \infty} h = \sin m_1 \theta \sin m_2 \psi, \quad \lim_{R \rightarrow \infty} g = \sin m_1 \theta \cos m_2 \psi, \quad \lim_{R \rightarrow \infty} f = \cos m_1 \theta. \quad (60)$$

The topological charge now reduces to a three dimensional integral in the residual coordinates $x_\mu = (r, s, t)$

$$\begin{aligned} I_5^{\text{bi-azim}} &= \eta^5 5 (2\pi)^2 n_1 n_2 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \partial_\mu \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C dr ds dt \\ &= \eta^5 5 (2\pi)^2 n_1 n_2 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C dS_\mu, \end{aligned} \quad (61)$$

in which the triplet function Ξ^A , $A = 1, 2, 3$ is defined as

$$\Xi^A = ((h)^2, (g)^2, f).$$

The surface integral (61) is then performed to yield

$$I_5^{\text{bi-azim}} = \eta^5 4! n_1 n_2 [1 - (-1)^{m_1}], \quad (62)$$

describing both multisolitons and soliton antisolitons.

4.5 Tri-azimuthal symmetry

This pertains to $D = 6$ only. The asymptotic behaviours of the functions h , g and f in the Ansatz (41) are taken to be

$$\begin{aligned} \lim_{R \rightarrow \infty} h &= \sin m_1 \psi_1 \sin m_2 \psi_2 \\ \lim_{R \rightarrow \infty} g &= \sin m_1 \psi_1 \cos m_2 \psi_2 \\ \lim_{R \rightarrow \infty} f &= \cos m_1 \psi_1. \end{aligned} \quad (63)$$

The topological charge integral in this case is

$$\begin{aligned} I_6^{\text{tri-azim}} &= \eta^6 90 (2\pi)^3 n_1 n_2 n_3 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \partial_\mu \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C d\rho d\sigma d\tau \\ &= \eta^6 90 (2\pi)^3 n_1 n_2 n_3 \int \varepsilon_{\mu\nu\rho} \varepsilon^{ABC} \Xi^A \partial_\nu \Xi^B \partial_\rho \Xi^C dS_\mu, \end{aligned} \quad (64)$$

where we have used the notation $x_\mu = (\rho, \sigma, \tau)$, and $\Xi^A = ((h)^2, (g)^2, (f)^2)$.

To evaluate the surface integral (64) we need analytic information which comes from finite energy conditions. While we are not displaying here the energy density functional in terms of the functions (h, g, f) , it is nonetheless easy to deduce that $h(\psi_1 = 0, \psi_2 = 0) = 0$, $g(\psi_1 = 0, \psi_2 = \frac{\pi}{2}) = 0$ and $f(\psi_1 = \frac{\pi}{2}) = 0$. These, together with continuity conditions, imply

that the flux (64) out of the three quarter planes (ρ, σ) , (σ, τ) and (τ, ρ) vanishes, and hence the only contribution comes from the surface bounding the octant of the two-sphere with radius $R = \sqrt{\rho^2 + \sigma^2 + \tau^2}$.

Applying the boundary functions (63) on the asymptotic octant the flux (64) yields

$$I_6^{\text{tri-azim}} = \frac{5! \pi^3}{2} n_1 n_2 n_3 \left(\frac{1}{2} [1 - (-1)^{m_1}] \right)^4 \left(\frac{1}{2} [1 - (-1)^{m_2}] \right)^2, \quad (65)$$

analogous to (59), like which the topological charge vanishes when either m_1 or m_2 is *even*, and otherwise it is given by the product of the vortex numbers pertaining to each of the azimuthal symmetries imposed.

5 Numerical constructions

In this Section we give numerical evidence for the existence spherically symmetric, and axially symmetric solutions in $D = 4, 5$. In addition we have constructed solutions with bi-azimuthal symmetry in $D = 4$. The solutions of the corresponding $D = 3$ model were presented in [11] to which we refer for the latter.

Of course, the most interesting solutions from the viewpoint of understanding zero topological charge, are the axially symmetric ones, but the spherically symmetric ones are also presented mainly because the equations of motion in that case allow a thorough asymptotic analysis underpinning the numerical work. Also the spherically symmetric solutions present useful starting profiles for the $D = 4$ bi-azimuthally symmetric multi-solitons.

Technically, we have restricted ourselves to two dimensional numerical integration, solutions with azimuthal symmetry in $D \geq 4$ representing a difficult numerical challenge which we leave for future work. Also, one should notice that only one coupling constant λ_i is relevant here. For example, one may factorize λ_1 and, by using a suitable rescaling, one may set $\lambda_2 = 1$ or $\lambda_3 = 1$ without any loss of generality.

To simplify the picture, in this section we shall note $\theta_{D-2} = \theta$ and $x_D = z$. Also, for all configurations, the total mass/energy M (which equals the total action) is computed by integrating the corresponding reduced energy functionals.

5.1 Spherically symmetric solutions

Considering the ansatz (26), the reduced one dimensional energy functional reads

$$E = R^{D-1} \mathcal{E} = R^{D-1} \left(\lambda_1 (Q^2 - 1)^4 \left(Q^2 + (D-1) \frac{Q^2}{R^2} \right) + 2(D-2) \lambda_2 (Q^2 - 1)^2 \frac{Q^2}{R^2} \right. \\ \left. \times \left(2Q^2 + (D-2) \frac{Q^2}{R^2} \right) + 6\lambda_3 (D-1)(D-2) \frac{Q^4}{R^4} \left(3Q^2 + (D-3) \frac{Q^2}{R^2} \right) \right) \quad (66)$$

Figure 1: The scalar function Q and energy density E of two typical $D = 4$ and $D = 5$ spherically symmetric solutions with $\lambda_1 = 1$ are shown as a function of the compactified radial coordinate $R/(1 + R)$.

which leads to the following differential equation

$$\left[2R^{D-1}Q' \left(\lambda_1(Q^2 - 1)^4 + 4\lambda_2(D - 2)(Q^2 - 1)^2\frac{Q^2}{R^2} + 18\lambda_3(D - 1)(D - 2)\frac{Q^4}{R^4} \right) \right]' \\ = R^{D-2} \left(2\lambda_1(Q^2 - 1)^3(4Q'^2 + 5(D - 1)\frac{Q^2}{R^2} - \frac{(D-1)}{R^2}) + 4\lambda_2\frac{(D-1)}{R^2}Q(Q^2 - 1) \right. \\ \left. + 36\lambda_3\frac{(D-1)(D-2)}{R^4}Q^3(2Q'^2 + (D - 3)\frac{Q^2}{R^2}) \right).$$

The solutions of this equation have been constructed numerically, for a range of the parameters λ_i . We follow the usual approach and, by using a standard ordinary differential equation solver, we evaluate the initial condition

$$Q(R) = bR - \frac{2b^3\lambda_1}{3(\lambda_1 + 12b^2(\lambda_2 + 9b^2\lambda_3))}R^3 + O(R^5), \quad \text{for } D = 4, \quad (67)$$

$$Q(R) = bR - \frac{2(b^3\lambda_1 + 4b^5\lambda_2 - 2)}{7(\lambda_1 + 16b^2\lambda_2 + 216b^4\lambda_3)}R^3 + O(R^5), \quad \text{for } D = 5 \quad (68)$$

at $R = 10^{-6}$ for global tolerance 10^{-14} , adjusting for the shooting parameter b and integrating towards $R \rightarrow \infty$. The behaviour of finite energy solutions for large values of R is

Figure 2: A three-dimensional plot of the reduced action density $E(R, \theta)$ of a $D = 5$, $m = 2$ axially symmetric solution with $\lambda_1 = \lambda_2 = 1$, $\lambda_3 = 75$.

$$Q(R) = 1 + ce^{-\frac{2}{3}\sqrt{\lambda_2/\lambda_3}r} - \frac{9\lambda_3}{4\lambda_2} \frac{1}{r^2} - \frac{243\lambda_3^2}{16\lambda_2^2} \frac{1}{r^4} + O(1/r^6), \text{ for } D = 4, \quad (69)$$

$$Q(R) = 1 + ce^{-\frac{2}{3}\sqrt{\lambda_2/\lambda_3}r} - \frac{9\lambda_3}{2\lambda_2} \frac{1}{r^2} + \frac{81\lambda_3^2}{2\lambda_2^2} \frac{1}{r^4} + O(1/r^6), \text{ for } D = 5, \quad (70)$$

where c is a free parameter (the corresponding expressions for the $D = 3$ model are given in [11]). For all cases considered, solutions with the correct asymptotics are found when the first derivative of the scalar function $Q(R)$ evaluated at the origin, $Q'(0) = b$, takes on a certain value, which is a function of λ_i .

The profiles of typical $D = 4, 5$ solutions are presented in Figure 1 for $\lambda_1 = \lambda_2 = \lambda_3 = 1$. The energy functional, as given by (66) is also exhibited (one should notice the different length scales of the $D = 4$ and $D = 5$ solitons). Similar to the $D = 3$ case, no multinode radial solutions were found, although we have no analytical argument for their absence.

5.2 Axially symmetric solutions

Scalar solitons with axial symmetry are found by taking $m \geq 2$ in the boundary conditions at infinity (43). The two-dimensional energy functional $E(R, \theta)$ and the set of two coupled non-linear elliptic partial differential equations satisfied by the functions $H(R, \theta)$, $G(R, \theta)$ can easily be derived by using the reduced building blocks (31) and we shall not present them

here. These equations are solved numerically, subject to the boundary conditions

$$H|_{R=0} = 0 \quad , \quad \partial_R G|_{R=0} = 0. \quad (71)$$

at the origin and (43) at infinity⁴ (we have restricted our analysis to $m = 2$ solutions; the $m = 1$ case corresponds to spherically symmetric configurations). Considering solutions with parity reflection symmetry, the equations are integrated in the $0 \leq \theta \leq \pi/2$ region. The boundary conditions satisfied at the limits of the θ -interval are

$$H|_{\theta=0} = \partial_\theta G|_{\theta=0} = 0, \quad \partial_\theta H|_{\theta=\pi/2} = G|_{\theta=\pi/2} = 0. \quad (72)$$

The absence of suitable starting profiles makes this problem extremely difficult. The numerical calculations were performed with the software package CADSOL/FIDISOL, based on the Newton-Raphson method [17].

Figure 3: The modulus of the scalar field $|\varphi| = \sqrt{H^2 + G^2}$ is shown as a function of the coordinates r and z for a typical $D = 4$, $m = 2$ axially symmetric solution.

The numerical error for the functions is estimated to be of the order of 10^{-2} or lower for most of the axially symmetric configurations.

Solutions with $m = 2$ of the corresponding $D = 3$ model were discussed in [11]. In that case it was possible to distinguish two individual components (e.g. the modulus of the scalar field $|\phi| = \sqrt{\phi_1^2 + \phi_2^2}$ possesses always two distinct zeros on the z axis).

⁴In the numerical algorithm we have employed a compactified radial coordinate $x = R/(1 + R)$, such that spatial infinity corresponds to $x = 1$.

Our $D = 4, 5$ results indicate that this is a generic feature of all axially symmetric solutions. In Figure 2 we present a three dimensional plot of the energy functional (the reduced Lagrangian) $E(R, \theta)$ of a typical $D = 5, m = 2$ axially symmetric solution as a function of the r, z (here $\lambda = \lambda_2 = 1, \lambda_3 = 75$). The modulus of the scalar field $|\varphi| = \sqrt{H^2 + G^2}$ of a $D = 4$ solution with $\lambda = \lambda_2 = 1, \lambda_3 = 8$ is presented in Figure 3. We have found that $|\varphi|$ possesses always two zeros at $\pm d/2$ on the z -symmetry axis, the positions of the nodes depending on the value of the coupling constants λ_i . The total action of these solutions, as given by the integral of $E(R, \theta)$ increases with increasing λ_i . Interestingly enough, the reduced Lagrangian density $E(R, \theta)$ possesses a saddle point at the origin, the maxima being localized at $z = \pm d/2$, at a nonzero value of $r, r = r_0$. This feature, already present in the $D = 3$ case (see Figure 4 in Ref. [11]) is enhanced for the higher dimensional configurations.

Although the profiles of the axially symmetric solutions look qualitatively the same for $D = 3, 4, 5$, their physical significance is very different. For $D = 4$ they describe two distinct solitons sitting at $(z = \pm d/2, r = r_0)$, while in three and five dimensions the solutions represent a pair of soliton-antisoliton with zero topological charge.

It would be interesting to construct higher m solutions, describing for an odd dimension soliton-anti-soliton chains, in analogy with the situation in YMH theory [9].

Figure 4: The profiles of the scalar functions φ_1 and φ_2 are shown for a typical $D = 4$ bi-azimuthally symmetric solution with $n_1 = n_2 = 2, \lambda_1 = \lambda_2 = \lambda_3 = 1$.

5.3 Solutions with bi-azimuthal symmetry

To obtain $D = 4$, $m = 1$ configurations with bi-azimuthal symmetry, we employ the $n = 1$ spherically symmetric solutions discussed in 5.1 above for starting profiles and increase the values of n_1 , n_2 slowly. The iterations converge, and repeating the procedure one obtains in this way solutions for arbitrary n . The physical values of n_1 , n_2 are integers. We have studied solutions with $1 \leq n_1, n_2 \leq 9$. The reduced action density $E(R, \psi)$ can be written in terms of the reduced building blocks (37). The two scalar functions $h(R, \psi)$ and $g(R, \psi)$ satisfy the boundary conditions

$$h|_{R=0} = g|_{R=0} = 0 \tag{73}$$

at the origin, (57) at infinity, and

$$h|_{\psi=0} = \partial_\psi g|_{\psi=0} = 0, \quad \partial_\psi h|_{\psi=\pi/2} = g|_{\psi=\pi/2} = 0. \tag{74}$$

on the ρ and σ axes. The field equations have been solved by using the same methods employed in the axially symmetric case but now with much better accuracy, the typical numerical error being of the order of 10^{-4} or smaller.

Figure 5: A three-dimensional plot of the effective lagrangean $E(\rho, \sigma)$ of the $D = 4$ bi-azimuthally symmetric solution presented in Figure 4.

As expected, the bi-azimuthally symmetric solutions exhibit a very different picture. A general feature of all $m = 1$ solutions with $n_1 = n_2$ is that the energy functional $E(R, \psi)$ possesses one maximum on the $\psi = \pi/4$ axis (corresponding to the $\rho = \sigma$ surface), it

being possible to distinguish only one individual concentration of the action. In this respect the bi-azimuthally symmetric multisolitons of this model are qualitatively similar to those of the models featuring gauge fields, as discussed recently in [10, 19]. In contrast to the latter however, where only solutions with $n_1 = n_2$ were found, here we noticed the existence finite mass solutions with $n_1 \neq n_2$. The maximum of the action density moves inward with increasing n_1, n_2 .

In Figure 4 the profiles scalar functions h and g of the a typical bi-azimuthally symmetric solution are shown for several angles as a function of the radial coordinate R (with $\lambda_1 = \lambda_2 = \lambda_3 = 1$ in this case). A three dimensional plot of the energy density of a typical $m = 1$, $n_1 = n_2 = 2$ configuration is presented in Figure 5. We have also studied the mass dependence of the bi-azimuthally symmetric solutions on the coupling constants λ_i . From the numerical results, we observed some features of the solutions, without attempting to give an analytic explanation. The most peculiar of these is the fact that finite mass solutions persist for a small but finite range of negative $\lambda_2 \leq 0$. No such solutions can be justified by the topological lower bounds. When λ_1 or λ_2 are varied, the maximum of the mass-energy density moves inwards with increasing value of the respective coupling constant, while the opposite behaviour to this is found when λ_3 is varied. Yet another property of multi-solitons is observed. It turns out that the mass of a solution $M(n_1, n_2)$, whose topological lower bound given by (59) to be $4\pi^2 n_1 n_2$, is quantitatively quite close to $n_1 n_2 M(1, 1)$. This means that the deviation of the value of $M(n_1, n_2)$ from its lower bound value is proportionate to the deviation of the value of $M(1, 1)$ from its respective lower bound value, implying that composite solitons have rather low binding energies. On the other hand, in all cases studied, it turns out that $M(n_1, n_2) > n_1 n_2 M(1, 1)$, albeit by a small amount quantitatively. This in turn suggests that the composite states are unstable against decay into the lowest mass constituents.

Yet another surprising but not counterintuitive property observed is, that while multi-solitons of masses $M(n_1, n_2)$ exhibit one single peak of the energy density for *small* values of $|n_1 - n_2|$, when $|n_1 - n_2|$ becomes *large* the energy density develops two separated peaks.

More complicated bi-azimuthal solutions with $m \geq 2$ are likely to exist. These configurations would describe composite bound states, rather analogous to the monopole-antimonopole chains of the Yang-Mills-Higgs model [9]. Our preliminary numerical results already indicate the existence of zero topological charge $m = 2$ configurations with bi-azimuthal symmetry in $D = 4$, with $n_1 = n_2 = 2$. We found that there were no $m = 2$ solutions with $n_1 = n_2 = 1$, just as for the pure YM model whose instanton-antiinstanton solutions constructed in [10]. Again as in [10], the energy density exhibits two distinct maxima on the $\psi = \pi/4$ axis. In the absence of suitable starting profiles however, the numerical accuracy of these solutions turned out to be much lower in this case.

A systematic discussion of these solutions, together with a generalisation to higher dimensions will be presented elsewhere.

6 Summary and Conclusions

The overriding aim of this work is to examine the conditions that enable the construction of zero topological charge solutions in classical field theories, which otherwise support topologically stable (multi-)soliton solutions with nonvanishing topological charge. We have shown that the conditions in question are those of (a) subjecting the system to the requisite symmetry, which in practice is what is done anyway when constructing (multi-)solitons, and (b) by requiring special types of boundary conditions that differ essentially from those employed for (multi-)solitons.

Our symmetry analysis covers dimensions $D = 3, 4, 5, 6$, namely both odd and even examples in $6 \geq D \geq 3$, while the solutions constructed numerically to underpin our findings are limited to $D \leq 5$. The reason for this restriction is that boundary value problems in more than two dimensions is beyond the scope of the present work. The case $D = 2$ is irrelevant, being too small to accommodate requirements (a) and (b). The case $D = 3$, while it is the first nontrivial example, is rather special since in that case *axial* and *azimuthal* symmetries coincide. We have chosen to carry out this investigation in the framework of the simplest possible field theoretic model, irrespective of its applicability to physical problems. This is a symmetry breaking Goldstone type model in D Euclidean dimensions, whose energy density functional depends on a D component scalar field ϕ^a , $a = 1, 2, \dots, D$. This choice is motivated by the fact that the topological charges in such models are the simplest available examples, being up to constant multiples the *winding numbers* of ϕ^a in \mathbb{R}^D . It should be emphasised however that our conclusions hold in the other classical field theories that support solitons in these dimensions, namely the sigma models and the non Abelian gauge field systems (including Higgs fields).

Our conclusions can be summarised as follows:

- The field ϕ^a asymptotically tends to a unit vector $\hat{\phi}^a$, which depends exclusively on angular variables, the radial variable being infinite. Precisely what these angular variables are depends on the symmetry imposed. To analyse qualitatively distinct possibilities, we have found it sufficient to impose symmetries that result in residual subsystems of no more than **three** dimensions. It is superfluous to consider weaker symmetries resulting in four or higher number of effective degrees of freedom, since these do not result in qualitatively new features as far as the existence of multisolitons, and soliton–antisoliton chains is concerned.
- There are two types of symmetries employed. First, spherical (rotational) symmetry in a N dimensional subspace of \mathbb{R}^D . For $N = D - 1$, this is *axial* symmetry resulting in *two* effective degrees of freedom. At the other extreme, $N = 2$, this is *azimuthal* symmetry resulting in an effective $D - 2$ dimensional subsystem. Accordingly, we have restricted to $D = 3, 4$ in the case of *azimuthal* symmetry. Intermediate values of N subject to this restriction are, $N = 3$ in $D = 5$ and $N = 4$ in $D = 6$. We have described these as *intermediate* symmetries. Second, we impose *multi-azimuthal* symmetries, composed of azimuthal symmetries in pairs of coordinates. Again, subject to limiting our considerations to three effective degrees of freedom, these are *bi-azimuthal*

symmetry in $D = 4, 5$, and *tri-azimuthal* symmetry in $D = 6$. The residual system after symmetry imposition depends on the radial coordinate and the remaining angular coordinates, and the number of unknown functions is the same as the dimensionality of the residual subsystem. In all cases, the azimuthal angles are all integrated out and the remaining angular dependence is on *polar* angles $\{\theta_i\}$ ($0 \leq \theta \leq \pi$) and *semi-polar* angles $\{\psi_I\}$ ($0 \leq \psi_I \leq \frac{\pi}{2}$), i and I labeling the residual polar and semi-polar angles, respectively.

- The asymptotic field $\hat{\phi}^a$ is parametrised by the residual angular variables $\{\theta_i\}$ and $\{\psi_I\}$ only. The other angular variables, that include **all** *azimuthal* angles, are integrated out. Consistently with the requirements of finite energy and analyticity, the most general as $\hat{\phi}^a$ is encoded by $\{\theta_i\}$ and $\{\psi_I\}$ is via

$$\{m_i \theta_i\} \quad , \quad \{m_I \psi_I\} \quad , \quad m_i, m_I \text{ integers} . \quad (75)$$

It is important to stress that the integers (m_i, m_I) in (75) appear **only** in the asymptotic field $\hat{\phi}^a$, and that they **do not** parametrise the field ϕ^a everywhere. Throughout this text, we have reserved the letter m to these m -numbers. In contrast we label the *vorticity* associated with each azimuthal symmetry, on which the field ϕ^a everywhere depends, by the letters $\{n\}$. Thus the n -numbers which count the winding in each azimuthal plane are on a completely distinct footing as opposed to the m -numbers which serve only to select the boundary values imposed. All solutions with $m = 1$ describe topologically stable multisolitons whose topological charges are encoded with the n -numbers, $\{n\}$. The topological charges of soliton-antisoliton chains with even m are *zero*, while those of odd m are *nonzero*, and depend on $\{n\}$. In the special case of axial symmetry in $D \geq 4$, when no n -number occurs, the topological charges in even D are labeled by a m -number.

The numerical constructions in Section 5 underpin the above conclusions. Both (multi)solitons and soliton-antisoliton solutions have been constructed like for the $D = 3$ case in [11], whose results are extended to higher dimensions than the present work. Various features found there are shared by higher dimensional axially symmetric solutions. In particular the profiles of the scalar functions have rather similar shapes. The numerical constructions in the present work is limited to 2 dimensional boundary value problem involving 2, so that we present only axially symmetric solutions in $D = 4, 5$ (and $D = 3$ in [11]), and bi-azimuthally symmetric solutions in $D = 4$.

The axially symmetric solutions constructed in both [11] and in section 5.2 here are limited in their scope to solutions with asymptotic behaviour characterised by m -number equal to 1 and to 2. In the $D = 3$ case [11] these are multisolitons with $m = 1$ and higher n -numbers, and to soliton-antisoliton pairs with $m = 2$ and n -number equal to 1. In $D = 3$, like for the YMH monopoles [18] the energy density of the multisolitons is concentrated at the origin, and when $m = 2$ there occur two concentrations distributed symmetrically on the 3-axis. While we expect that solitons with $m \geq 2$ and with $n = 1$ would describe chains of solitons and antisolitons on the 3-axis, and when $n \geq 3$ rings

would form, like for the monopoles in the YMH model observed in [9], this has not been carried out in [11]. Here, axially symmetric solutions in $D = 4, 5$ are constructed in section **5.2**. The $m = 2$ solutions in $D = 5$ are similar to the $m = 2, n = 1$ soliton–antisoliton solutions in $D = 3$, *i.e.* they describe two distinct peaks on the 5–axis of equal and opposite charges. But there is no n –number in $D = 5$ so here the analogy with $D = 3$ stops. The $m = 2$ axially symmetric solutions in $D = 4$ also describe two peaks on the 4–axis, but unlike those of $D = 3, 5$ they both peaks have the same topological charge. These are multisolitons, qualitatively similar to the axially symmetric Witten multiinstantons [12]. This illustrates that for axially symmetric fields with m –number higher than 1, the peaks are situated on the (symmetry) D –axis, such that in odd dimensions their charges have alternating signs, while in even dimensions all the charges have the same sign.

There is one final property of axially symmetric solutions worth remarking on. In gauge field systems, namely the $D = 3$ monopole [?] as our only example, the the zero charge $m = 2$ solutions have a positive binding energy with respect to decay into two charge–1 monopoles. By contrast, the multisolitons and the soliton–antisoliton solutions of the Goldstone models have negative binding energies. We have not given quantitative evidence of this in section **5.2** because of insufficient numerical accuracy, but this qualitative trend was observed.

The bi-azimuthally symmetric solutions in $D = 4$ constructed in section **5.3** have their analogue in the bi-azimuthal YM instantons given in [10]. Like in that case there is a n –number associated with each (of the two) azimuthal symmetries, n_1 and n_2 , and the topological charge is proportional to $n_1 n_2$ (see (62)). Unlike in [10] however, where finite action solutions occur only for one interger $n_1 = n_2 = n$, here there are solutions for distinct $n_1 \neq n_2$. For m –number equal to 1 with $n_1 = n_2 = n$ the action density has only one peak which like in the YM example [10] is not situated at the origin. Rather, it peaks at a numerically determined distance from the origin on the $\psi = \frac{\pi}{4}$ axis, ψ being the unique semi–polar angle. The situation is different in the ($m = 1$) $n_1 \neq n_2$ case. There the action density breaks up into two distinct peaks on the $\psi = \frac{\pi}{4}$ axis, and the centres of these peaks move away from each other as $|n_1 - n_2|$ increases. Another point of contrast with the YM case, where the multiinstantons do form bound states, the corresponding multisolitons here do not form bound states. For all configurations we have studied, the energy of a the n_1, n_2 multi–solitons of our model are greater than that of $n_1 n_2$ 1-solitons. Moreover it turns out that this deficit of binding energy increases with increasing n_1, n_2 . We have also verified that $m = 2$ solutions carrying zero topological charge (see (62)) exist, in the $n_1 = n_2 = 2$ case, but have not supplied quantitative data here. These present two distinct peaks like in the YM case [10]. Our numerical results here were not sufficiently accurate to enable us to estimate wheter the binding energy preventing the decay of this solution into two charge–2 ($m = 1$) multisolitons is positive or negative. Likewise for the same reason, we did not increase n_1 and n_2 to values higher than 3, to see what the analogues of the rings forming in the $D = 3$ YM example [8] are. (Such ring like configurations were discovered recently in the bi-azimuthal gauge field configurations with $n = 3$ in [19], implying their occurrence here.)

This completes the summary of our results. We now make some final, general comments. We have seen that most of the geometrical and topological properties of the multisoliton

and soliton–antisoliton solutions in the Goldstone models studied here, are broadly similar both to the YMH example [8, 9] in $D = 3$ and to the YM example [10] in $D = 4$. There are however some notable differences, firstly that the binding energies of our multisolitons are negative as opposed to those of their gauge field counterparts [8, 9, 10], which are positive. Then there is the difference between the $D = 4$ bi-azimuthal Goldstone solitons, where the two vorticities (n -numbers) can be different, and the $D = 4$ YM instantons for which the two vorticities must be equal. More recently the $SU(2)$ YM-dilaton system in $4 + 1$ dimensions was analysed and the static bi-azimuthally symmetric solutions were studied in [19]. There too, the numerical results indicated that the two n -numbers had to be equal $n_1 = n_2$. It appears therefore that this restriction ($n_1 = n_2$) applies to bi-azimuthally symmetric gauge fields, but not to Goldstone fields. It is likely this feature may persist in multi-azimuthal systems too, but since this conclusion is reached only on the basis of numerics, it is beyond the scope of the present work.

Based on what we have learnt about the general similarities in the different models supporting topologically nontrivial lumps studied here and in [8, 9, 10, 19], we would speculate that similar analogous properties can be expected for the lump solutions in various sigma models, *e.g.* $O(D + 1)$ models on \mathbb{R}^D , or the corresponding Grassmannian sigma models on \mathbb{R}^{2N} , or indeed their gauged counterparts. One respect in which it would have been more appropriate to use $O(D + 1)$ models on \mathbb{R}^D instead of Goldstone models, featuring negative binding energies, is that the $O(D + 1)$ models would be expected to feature positive binding energies, based on our knowledge of the $O(3 + 1)$ model on \mathbb{R}^3 , namely the celebrated Skyrme model. Certainly the simple analysis of the topological charges and boundary conditions given in section 4 can be extended systematically and without obstacles to the sigma model counterparts of the scalar Goldstone fields. This was eschewed because the numerical constructions for the sigma models, in particular the practical task of imposing the boundary conditions, are very much harder.

One last comment concerns a common feature of zero topological charge bi-azimuthal solutions to both gauge field systems, namely those studied in [10, 19], and to the corresponding Goldstone model studied here. These are both solutions with m -number equal to 2. In the former case, the numerical results indicated that the simplest such solution was that with n -number equal to 2, and not $n = 1$. Likewise in the case at hand, it turned out that there existed no solution for $n_1 = n_2 = 1$, the simplest solution being characterised by $n_1 = 1$, $n_2 = 2$. It is interesting that this observation is consistent with the results of the numerical analysis of Krusch and Sutcliffe [20] in the context of the zero baryon charge solutions of the Skyrme model. It is very interesting also that the analytic analysis of Sadun and Segert SS2, which proves the existence of non-selfdual instantons (*e.g.* our $m = 3$ instantons [10]), their proof exculdes topological charge 1 instantons (*e.g.* our $m = 3$ instantons with $n = 1$ whose topological charge is equal to $n^2 = 1$). This is a rather subtle but pervasive feature, which we cannot analyse further here.
