A Standard Model for the FQHE

An effective quantum field theory in the low-energy (IR) regime

- It needs to be based on phenomenological and numerical evidences.
- It cannot be derived from any high-energy quantum field theory (quantum gravity, etc.).
- It has to incorporate topological and non-topological (geometric) features of the FQHE.
- It has to take into account not only topological order, but also nematic, ferromagnetic, superconducting (etc.) phases.
- It has to be a predictive (and not just a descriptive) theory.

Chern-Simons theory in the Integer Quantum Hall Effect

U(1) Chern-Simons theory in the IQHE

$$S_{CS}[A] = \int d^3x \, \left(rac{
u}{4\pi} \epsilon^{\mu
u\lambda} A_\mu \partial_
u A_\lambda + j^\mu A_\mu
ight),$$

Hall current ($e^2/\hbar \equiv 1$):

$$J^{i} = \frac{\nu}{2\pi} \epsilon^{ij} E_{j}$$

- Quantized Hall conductivity with filling factor $\nu \in \mathbb{Z}$

Chern-Simons theory in the Abelian Laughlin states

Coulomb interactions give rise to the fractionalization of the electric charge, $\nu = \frac{1}{p}$, with p a positive odd number.

$$S_{CS}[a,A] = \int d^3x \left(rac{1}{2\pi} \epsilon^{\mu
u\lambda} A_\mu \partial_
u a_\lambda - rac{p}{4\pi} \epsilon^{\mu
u\lambda} a_\mu \partial_
u a_\lambda + ...
ight).$$

By integrating out the hydro-dynamical field a_{μ} we obtain the correct fractional Hall conductivity

$$S_{CS}[A] = \int d^3x \left(\frac{1}{4\pi\rho} \epsilon^{\mu\nu\lambda} A_{\mu} \partial_{\nu} A_{\lambda} \right) \, .$$

On a disk geometry, the edge theory is given by a chiral boson action in polar coordinates (t, ϕ)

$$S_{\varphi} = \frac{1}{2} \int d\phi \, dt \, \left[\partial_t \varphi \partial_\phi \varphi + v_b (\partial_\phi \varphi)^2 \right],$$

namely a chiral CFT with c = 1.

FQHE on curved space and Hall viscosity

The Hall viscosity comes from the response of the system to shear or strain. From a suitable effective topological action $S[a, A, \omega]$, with ω the SO(2) spin connection, we integrate out a and obtain

$$S[\omega, A] = \int \left[\left(\frac{\nu \bar{s}^2}{4\pi} - \frac{c}{48\pi} \right) \omega d\omega + \frac{\nu}{4\pi} A dA + \frac{\nu \bar{s}}{2\pi} A d\omega \right],$$

$$ho = rac{
u}{2\pi}B + rac{
uar{s}}{4\pi}R, \qquad J^i = rac{
u}{2\pi}\epsilon^{ij}E_j + rac{
uar{s}}{2\pi}\epsilon^{ij}\mathcal{E}_j,$$

where $\bar{s} = p/2$ is the average orbital spin (shift).

$$s^{\mu} = rac{
uar{s}}{2\pi}\epsilon^{\mu
u\lambda}\partial_{
u}A_{\lambda} + \left(rac{
uar{s}^2}{2\pi} - rac{c}{24\pi}
ight)\epsilon^{\mu
u\lambda}\partial_{
u}\omega_{\lambda},$$

where

$$\frac{\nu\bar{s}}{2\pi}\epsilon^{\mu\nu\lambda}\partial_{\nu}A_{\lambda}=\eta_{H}u^{\mu},$$

with u^{μ} the covariant drift velocity and $\eta_{H} = \nu \bar{s}B/4\pi$ the Hall viscosity.

Incompressibility and area-preserving diffeomorphisms

The incompressibility of the FQH fluid is due to an underlying quantum area-preserving diffs induced by interactions.

$$H_{V} = \int d^{2}q \, V_{q} \bar{\rho}_{-q} \bar{\rho}_{q},$$
$$\bar{\rho}_{\tilde{q}}, \bar{\rho}_{q}] = f(\tilde{q}, q) \bar{\rho}_{\tilde{q}+q}, \quad f(\tilde{q}, q) = 2i \, e^{\tilde{q} \cdot q} \sin\left(\frac{\tilde{q} \times q}{2}\right).$$

The projected density operators $\bar{\rho}_{q}$ on the lowest Landau level satisfy the Girvin-MacDonald-Platzman (GMP)/ W_{∞} algebra. GMP mode: $|q\rangle = \bar{\rho}_q |0\rangle$ ($|0\rangle$ is the exact ground state of H_V). It is possible to show that the GMP mode is a massive spin-2

From the GMP mode to emergent geometry

Emergent geometry in the FQHE induced by interactions (Haldane, PRL (2011)).

- Being topological, Chern-Simons theories cannot encode dynamical massive gravitons.
- TQFTs have to be embedded in a more general framework that should be able to encode both topological and geometric features of the FQHE.
- Non-relativistic bimetric theory: $(g_{\mu\nu}, \hat{g}_{\mu\nu})$ (Gromov and Son, PRX (2017)).
- The GMP algebra give rise to higher-spin modes (S. Golkar, D. X. Nguyen, M. M. Roberts, D. T. Son, PRL (2016), Randellini and Cappelli, JHEP (2016)).

For the filling factor $\nu = 1/2$, Moore-Read state describes composite fermions which pair up and condense by giving rise to a p-wave superconductor (Moore and Read, NPB, (1991)).

- Quasi-particles have fractional charge e/4.
- Non-Abelian Ising anyons in the bulk.
- A massless chiral Majorana mode appears together with the chiral boson on the boundary.
- Effective field theory:

 $SU(2)_2$ Chern-Simons theory in the bulk and $SU(2)_2$ chiral WZW on the boundary, with c = 3/2 = 1 + 1/2.

It has been recently conjectured that the chiral Majorana fermion ψ and chiral boson φ are superpartners and described by a $\mathcal{N} = (1,0)$ supersymmetric conformal field theory (K.W. Ma, R. Wang, and K. Yang, PRL, (2021)).

$$S[\varphi,\psi] = \frac{1}{2} \int d\phi \, dt \, \left[\partial_t \varphi \partial_\phi \varphi + \mathbf{v}_b (\partial_\phi \varphi)^2 + i \psi (\partial_t + \mathbf{v}_f \partial_\phi) \psi \right],$$

SUSY is broken when $v_b \neq v_f$ and a goldstino emerges.

There exists a previous proposal with $\mathcal{N} = 2$ SCFT for the Moore-Read state (E. Sagi and R. A. Santos, PRB (2017)), which is compatible with the fermionization of the $SU(2)_2$ WZW model (J.-B. Bae and S. Lee, arXiv:2105.02148).

Neutral spin-3/2 collective mode

B. Yang, Z.-X. Hu, Z. Papic, and F. D. M. Haldane, PRL (2012).Magneto-Rotor (MR)=GMP mode, NF=neutral fermion mode.

These two modes can be seen as superpartners of each other (Gromov, Martinec and Ryu, PRL (2020)).

Global symmetries and features in the Moore-Read state

Magnetic translations (broken time-reversal symmetry)

- Galilei rotational invariance
- Supersymmetry
- TQFT at ground state

Superalgebra and first-order formalism in (super-)geometry

$$[\mathcal{J}, \mathcal{P}_{a}] = \epsilon_{a}{}^{b}\mathcal{P}_{b}, \quad [\mathcal{P}_{a}, \mathcal{P}_{b}] = -\epsilon_{ab}\mathcal{T},$$
$$[\mathcal{J}, \mathcal{Q}_{\alpha}] = \frac{1}{2} (\gamma_{0})^{\beta}{}_{\alpha}\mathcal{Q}_{\beta}, \quad \{\mathcal{Q}_{\alpha}, \mathcal{Q}_{\alpha}\} = \frac{1}{2} (C\gamma_{0})_{\alpha\beta}\mathcal{T},$$
$$[\mathcal{Z}, \mathcal{P}_{a}] = \epsilon_{a}{}^{b}\mathcal{P}_{b}, \quad [\mathcal{Z}, \mathcal{Q}_{\alpha}] = \frac{1}{2} (\gamma_{0})^{\beta}{}_{\alpha}\mathcal{Q}_{\beta},$$

 Q_{α} are Majorana supercharges, $C_{\alpha\beta} = \epsilon_{\alpha\beta}$ is the charge conjugation matrix. The Nappi-Witten algebra is a subalgebra.

$$\langle \mathcal{J}, \mathcal{J} \rangle = \mu_{0}, \quad \langle \mathcal{P}_{a}, \mathcal{P}_{b} \rangle = \mu_{1} \delta_{ab}, \quad \langle \mathcal{J}, \mathcal{T} \rangle = -\mu_{1}, \\ \langle \mathcal{Q}_{\alpha}, \mathcal{Q}_{\beta} \rangle = \mathcal{C}_{\alpha\beta} \mu_{1}, \quad \langle \mathcal{Z}, \mathcal{J} \rangle = \mu_{1}, \quad \langle \mathcal{Z}, \mathcal{T} \rangle = -\mu_{1}, \\ \langle \mathcal{Z}, \mathcal{Z} \rangle = \mu_{2},$$

$$\mathbb{A} = \omega \mathcal{J} + a \mathcal{Z} + e^a \mathcal{P}_a + A \mathcal{T} + \mathcal{Q}_\alpha \Psi^\alpha.$$

Chern-Simons theory and non-relativistic supergeometry

$$S_{\mathrm{CS}} = rac{1}{4\pi} \int \left\langle \mathbb{A} d\mathbb{A} + rac{2}{3} \mathbb{A} \wedge \mathbb{A} \wedge \mathbb{A}
ight
angle,$$

$$\mathbb{F} = d\mathbb{A} + (1/2)[\mathbb{A}, \mathbb{A}] = R\mathcal{J} + f\mathcal{Z} + R^{a}\mathcal{P}_{a} + F\mathcal{T} + \mathcal{Q}_{\alpha}D\Psi^{\alpha}.$$

$$R = d\omega, \qquad f = da,$$

$$R^{a} = de^{a} + \epsilon^{a}{}_{b}e^{b}(\omega + a),$$

$$F = dA - \frac{1}{2}\epsilon_{ab}e^{a}e^{b} - \frac{1}{4}\bar{\Psi}_{\alpha}(\gamma_{0})^{\alpha}{}_{\beta}\Psi^{\beta},$$

$$D\Psi^{\alpha} = d\Psi^{\alpha} + \frac{1}{2}(\omega + a)(\gamma_{0})^{\alpha}{}_{\beta}\Psi^{\beta}.$$

$$S_{\rm CS} = \frac{1}{4\pi}\int \left[\mu_{0}\omega \,d\omega + 2\mu_{1}\,ad\omega + \mu_{2}\,ada + \mu_{1}\,e^{a}R_{a} - 2\mu_{1}\,Ad(\omega + a) - \mu_{1}\bar{\Psi}_{\alpha}D\Psi^{\alpha}\right].$$

Boundary theory: chiral boson and chiral Majorana mode

$$S_{\mathrm{WZW}} = rac{1}{4\pi} \int dt d\phi \left\langle g^{-1} \partial_+ g g^{-1} g' \right\rangle - rac{1}{12\pi} \int_{\mathcal{M}_3} \left\langle \left(g^{-1} \mathrm{d} g
ight)^3 \right\rangle,$$

with $\partial_{\pm} = \partial_t \pm v \partial_{\phi}$ and $g' \equiv \partial_t g$, which is obtained after replacing the local solution of the CS field equations $\mathbb{F} = 0$, given by $\mathbb{A} = g^{-1} dg$ with the boundary condition $\mathbb{A}_t + v \mathbb{A}_{\phi} = 0$ back in the action. The left-invariant Maurer-Cartan form

$$\Omega = g^{-1} dg = \Omega_{\mathcal{J}} \mathcal{J} + \Omega_{\mathcal{Z}} \mathcal{Z} + \Omega_{\mathcal{P}}^{\mathsf{a}} \mathcal{P}_{\mathsf{a}} + \Omega_{\mathcal{T}} \mathcal{T} + \mathcal{Q}_{\alpha} \Omega_{\mathcal{Q}}^{\alpha},$$

satisfies the Maurer-Cartan equation

 $d\Omega + \Omega \wedge \Omega = 0.$

くしゃ (雪) (雪) (雪) (雪) (雪) (

$$S_{\mathrm{WZW}} = rac{1}{4\pi}\int dt d\phi iggl(ilde{\mu}\,\partial_+arphiarphi' + \mu_1\psi_lpha\partial_+\psi^lphaiggr),$$

with $ilde{\mu} = (\mu_2 - 2\mu_1 + \mu_0).$

Broken supersymmetry and goldstino in the bulk

$$\mathcal{S}_\eta = rac{i\,\mu_1}{4\pi}\int Dar\eta\wedge\hat\gamma\wedge\,D\eta,$$

where η is a goldstino spinor field describing a neutral fermion and $\bar{\eta} = \eta^{\dagger} \gamma_0$ its conjugate, D is the covariant derivative and $\hat{\gamma} = e^a \gamma_a$. It looks a bit different from the standard 2+1-D Volkov-Akulov goldstino (Bansal and Sorokin, JHEP (2018)).

Goldstino-gravitino minimal coupling:

$$D\eta \to D\eta - \sqrt{m}\Psi, \quad D\bar{\eta} \to D\bar{\eta} - \sqrt{m}\bar{\Psi}.$$

$$S_m = rac{i\,\mu_1\,m}{4\pi}\int \bar{\Psi}\wedge\hat{\gamma}\wedge\Psi,$$

This is the standard 2+1-D Rarita-Schwinger mass term that breaks SUSY (Deser, 1984).

We assume that *m* is large and positive such that we can neglect the terms that couple η and Ψ (they are proportional to \sqrt{m} , which is small compared to *m*).

By integrating out the massive gravitino $\boldsymbol{\Psi},$ we finally obtain a CS term

$$(\mu_1/4\pi)(\omega + a)d(\omega + a).$$

Moreover, in order to have a unique geometric response from the background geometry, we vary the action with respect to the spatial dreibein e^a to obtain the field equation $R_a = 0$, which in turn yields the following equation for torsion

$$T^{a} \equiv de^{a} + \epsilon^{a}{}_{b}e^{b}\omega = -\beta\epsilon^{a}{}_{b}e^{b}a.$$

$$S[A,\omega] = rac{1}{4\pi} \int \left[\hat{c} \,\omega d\omega + \nu \,A dA +
u S \,A d\omega
ight]$$

Here, for the Moore-Read state, $\hat{c} = (\nu - c)/12$, where $\nu = 1/2$, $\mathcal{S} = 3, \ c = 3/2$.

The exact values of these physical coefficients are derived by taking $\mu_0 = \hat{c} - \nu S/2$, $\mu_1 = -\nu S/2$ and $\mu_2 = -\nu \left(S/2 + (S/2)^2\right)$ in our theory.

The first and third terms in the above action are known as gravitational Chern-Simons and Wen-Zee term, respectively. The former is associated to the gravitational anomaly, while the latter is related to the Hall viscosity η_{H} .

$$\rho = \frac{\nu}{2\pi}B + \frac{\nu S}{8\pi}R, \quad J^{i} = \frac{\nu}{2\pi}\epsilon^{ij}E_{j} + \frac{\nu S}{4\pi}\epsilon^{ij}\mathcal{E}_{j}.$$

Conclusions and outlook

- I have presented a novel non-relativistic supergeometric theory to describe the topological response of the Moore-Read state in the low-energy regime.
- This theory gives rise to a massive gravitino in the bulk and a chiral Majorana a chiral boson modes on the boundary in agreement with previous works.
- It is crucial to generalize our theory by including also the dynamical GMP mode (massive graviton) and the further hypothetical higher-spin modes.
- It would be very interesting to generalize our approach to the hierarchies of FQH states in the second Landau level build from the Moore-Read state (Bonderson-Slingerland states).
